This paper

This paper

- ▶ Rethinking transfers and debt policies when $\overline{r^f} < \overline{g} < \overline{r^K}$

This paper

- ▶ Rethinking transfers and debt policies when $\overline{r^f} < \overline{g} < \overline{r^K}$
- ▶ Is the economy *dynamically inefficient* in such environment?
Can a social planner generate a Pareto welfare improvement?
Yes.

This paper

- ▶ Rethinking transfers and debt policies when $\overline{r^f} < \overline{g} < \overline{r^K}$
- ▶ Is the economy *dynamically inefficient* in such environment?
Can a social planner generate a Pareto welfare improvement?
Yes.
- ▶ Does *dynamic inefficiency* imply an over-accumulation of capital?
No.

Literature

- ▶ On low rates: Mehrotra (2018), Rachel and Summers (2019)
- ▶ On *dynamic inefficiency* in OLG models:
 1. Samuelson (1958), Diamond (1965): $r^f < g$
 2. Abel et al. (1989): $r_t^K K_t \leq I_t \quad \forall t$
- ▶ On transfers and debt policies: Ball et al. (1998), Blanchard (2019), DeLong and Waldmann (2019)
- ▶ On risk-allocation in OLG models: Bohn (1998), Shiller (1999)

OLG model under uncertainty: Households

The model follows Blanchard (2019).

OLG model under uncertainty: Households

The model follows Blanchard (2019).

- ▶ **Environment.** Discrete time (One period = 25 years). Closed economy. Two overlapping cohorts of equal size alive at any point in time.

OLG model under uncertainty: Households

The model follows Blanchard (2019).

- ▶ **Environment.** Discrete time (One period = 25 years). Closed economy. Two overlapping cohorts of equal size alive at any point in time.
- ▶ **Preferences.** Households maximize their expected utility, given by the Epstein-Zin-Weil specification:

$$\mathbb{U}_t = (1 - \beta) \ln C_t^y + \beta \frac{1}{1 - \gamma} \ln \mathbb{E}[(C_{t+1}^o)^{1-\gamma}] \quad (1)$$

OLG model under uncertainty: Households

The model follows Blanchard (2019).

- ▶ **Environment.** Discrete time (One period = 25 years). Closed economy. Two overlapping cohorts of equal size alive at any point in time.
- ▶ **Preferences.** Households maximize their expected utility, given by the Epstein-Zin-Weil specification:

$$\mathbb{U}_t = (1 - \beta) \ln C_t^y + \beta \frac{1}{1 - \gamma} \ln \mathbb{E}[(C_{t+1}^o)^{1-\gamma}] \quad (1)$$

- ▶ **Budget constraints.** The budget constraints are:

$$C_t^y + I_t + D_t = W_t + X - T_t - \theta_t \quad (2)$$

$$C_{t+1}^o = R_{t+1} I_t + R_t^f D_t + T_{t+1} \quad (3)$$

OLG model under uncertainty: Firms

- **Production.** Two cases. In the Cobb-Douglas case:

$$Y_t = A_t K_{t-1}^\alpha L^{1-\alpha} \quad (4)$$

In the linear case:

$$Y_t = A_t(\alpha K_{t-1} + (1 - \alpha)L) \quad (5)$$

where $L = 1$, and A_t iid s.t. $\log(A) \sim \mathcal{N}(\mu, \sigma)$.

OLG model under uncertainty: Firms

- **Production.** Two cases. In the Cobb-Douglas case:

$$Y_t = A_t K_{t-1}^\alpha L^{1-\alpha} \quad (4)$$

In the linear case:

$$Y_t = A_t(\alpha K_{t-1} + (1 - \alpha)L) \quad (5)$$

where $L = 1$, and A_t iid s.t. $\log(A) \sim \mathcal{N}(\mu, \sigma)$.

- **Factor markets.** Factor markets are perfectly competitive.

In the Cobb-Douglas case: $R_t = \alpha A_t K_{t-1}^{\alpha-1}$ and $W_t = (1 - \alpha) A_t K_{t-1}^\alpha$

In the linear case: $R_t = \alpha A_t$ and $W_t = (1 - \alpha) A_t$

OLG model under uncertainty: Firms

- **Production.** Two cases. In the Cobb-Douglas case:

$$Y_t = A_t K_{t-1}^\alpha L^{1-\alpha} \quad (4)$$

In the linear case:

$$Y_t = A_t(\alpha K_{t-1} + (1 - \alpha)L) \quad (5)$$

where $L = 1$, and A_t iid s.t. $\log(A) \sim \mathcal{N}(\mu, \sigma)$.

- **Factor markets.** Factor markets are perfectly competitive.
In the Cobb-Douglas case: $R_t = \alpha A_t K_{t-1}^{\alpha-1}$ and $W_t = (1 - \alpha) A_t K_{t-1}^\alpha$
In the linear case: $R_t = \alpha A_t$ and $W_t = (1 - \alpha) A_t$
- **Capital motion.** Capital fully depreciates after one period: $\delta = 1$.

$$K_t = I_t \quad (6)$$

OLG model under uncertainty: Government

► **Policies.** The government can:

1. Implement inter-generational transfers and set T_t every period.
2. Issue risk-free debt D_0 and rollover debt D_t at the real interest rate R_t^f every period. Absent default:

$$D_t = R_{t-1}^f D_{t-1} \quad (7)$$

OLG model under uncertainty: Government

► **Policies.** The government can:

1. Implement inter-generational transfers and set T_t every period.
2. Issue risk-free debt D_0 and rollover debt D_t at the real interest rate R_t^f every period. Absent default:

$$D_t = R_{t-1}^f D_{t-1} \quad (7)$$

- **Default.** The tax is: $\theta_t = D_t - D^*$ if $D_t > \bar{D}$ and $\theta_t = 0$ otherwise. This strong assumption ensures that debt is perceived as perfectly safe by households.

OLG model under uncertainty: Households' decisions

- ▶ **Old households.** Consume all their income.

OLG model under uncertainty: Households' decisions

- ▶ **Old households.** Consume all their income.
- ▶ **Young households.** The maximization problem can be rewritten:

$$\max_{l_t, D_t} \mathbb{U} = (1 - \beta) \log(W_t + X - T_t - l_t - D_t - \theta_t) + \frac{\beta}{1 - \gamma} \log(\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]) \quad (8)$$

OLG model under uncertainty: Households' decisions

- ▶ **Old households.** Consume all their income.
- ▶ **Young households.** The maximization problem can be rewritten:

$$\max_{l_t, D_t} \mathbb{U} = (1 - \beta) \log(W_t + X - T_t - l_t - D_t - \theta_t) + \frac{\beta}{1 - \gamma} \log(\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]) \quad (8)$$

The first order condition with respect to l_t is:

$$\frac{1 - \beta}{(W_t + X - T_t - l_t - D_t - \theta_t)} = \beta \frac{\mathbb{E}_t[R_{t+1}(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{-\gamma}]}{\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]} \quad (9)$$

Similarly, the first order condition with respect to D_t is:

$$\frac{1 - \beta}{(W_t + X - T_t - l_t - D_t - \theta_t)} = \beta \frac{R_t^f \mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{-\gamma}]}{\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]} \quad (10)$$

OLG model under uncertainty: Households' decisions

- ▶ **Old households.** Consume all their income.
- ▶ **Young households.** The maximization problem can be rewritten:

$$\max_{l_t, D_t} \mathbb{U} = (1 - \beta) \log(W_t + X - T_t - l_t - D_t - \theta_t) + \frac{\beta}{1 - \gamma} \log(\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]) \quad (8)$$

The first order condition with respect to l_t is:

$$\frac{1 - \beta}{(W_t + X - T_t - l_t - D_t - \theta_t)} = \beta \frac{\mathbb{E}_t[R_{t+1}(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{-\gamma}]}{\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]} \quad (9)$$

Similarly, the first order condition with respect to D_t is:

$$\frac{1 - \beta}{(W_t + X - T_t - l_t - D_t - \theta_t)} = \beta \frac{R_t^f \mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{-\gamma}]}{\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{1-\gamma}]} \quad (10)$$

The safe interest rate, which is determined by the equilibrium of inelastic supply from the government and the demand from the *young* is:

$$R_t^f = \frac{\mathbb{E}_t[R_{t+1}(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{-\gamma}]}{\mathbb{E}_t[(R_{t+1}l_t + R_t^f D_t + T_{t+1})^{-\gamma}]} \quad (11)$$

Calibration: No Government Intervention

Closed-form solutions for steady-state rates:

Calibration: No Government Intervention

Closed-form solutions for steady-state rates:

- ▶ In the linear case:

$$R_t^f = \alpha e^{\mu + \frac{1}{2}\sigma^2 - \gamma\sigma^2} \text{ and } \mathbb{E}[R_{t+1}] = \alpha e^{\mu + \frac{1}{2}\sigma^2}$$

- ▶ In the Cobb-Douglas case:

$$R_t^f = \frac{\alpha}{\beta(1-\alpha)} e^{(\frac{\sigma^2}{1+\alpha} - \gamma\sigma^2)} \text{ and } \mathbb{E}[R_{t+1}] = \frac{\alpha}{\beta(1-\alpha)} e^{(\frac{\sigma^2}{1+\alpha})}$$

- ▶ In both cases, the log equity premium is:

$$\ln(\mathbb{E}[R_{t+1}]) - \ln(R_t^f) = \gamma\sigma^2$$

Calibration: No Government Intervention

Closed-form solutions for steady-state rates:

- ▶ In the linear case:

$$R_t^f = \alpha e^{\mu + \frac{1}{2}\sigma^2 - \gamma\sigma^2} \text{ and } \mathbb{E}[R_{t+1}] = \alpha e^{\mu + \frac{1}{2}\sigma^2}$$

- ▶ In the Cobb-Douglas case:

$$R_t^f = \frac{\alpha}{\beta(1-\alpha)} e^{(\frac{\sigma^2}{1+\alpha} - \gamma\sigma^2)} \text{ and } \mathbb{E}[R_{t+1}] = \frac{\alpha}{\beta(1-\alpha)} e^{(\frac{\sigma^2}{1+\alpha})}$$

- ▶ In both cases, the log equity premium is:

$$\ln(\mathbb{E}[R_{t+1}]) - \ln(R_t^f) = \gamma\sigma^2$$

- ▶ Calibration: $\alpha = 1/3$; $\sigma = 0.2$; $X = W^*$;
 $\beta = 0.325$ in linear; $\mu = 3$ in Cobb-Douglas (Blanchard (2019))

Calibration: No Government Intervention

Closed-form solutions for steady-state rates:

- ▶ In the linear case:

$$R_t^f = \alpha e^{\mu + \frac{1}{2}\sigma^2 - \gamma\sigma^2} \text{ and } \mathbb{E}[R_{t+1}] = \alpha e^{\mu + \frac{1}{2}\sigma^2}$$

- ▶ In the Cobb-Douglas case:

$$R_t^f = \frac{\alpha}{\beta(1-\alpha)} e^{(\frac{\sigma^2}{1+\alpha} - \gamma\sigma^2)} \text{ and } \mathbb{E}[R_{t+1}] = \frac{\alpha}{\beta(1-\alpha)} e^{(\frac{\sigma^2}{1+\alpha})}$$

- ▶ In both cases, the log equity premium is:

$$\ln(\mathbb{E}[R_{t+1}]) - \ln(R_t^f) = \gamma\sigma^2$$

- ▶ Calibration: $\alpha = 1/3$; $\sigma = 0.2$; $X = W^*$;
 $\beta = 0.325$ in linear; $\mu = 3$ in Cobb-Douglas (Blanchard (2019))

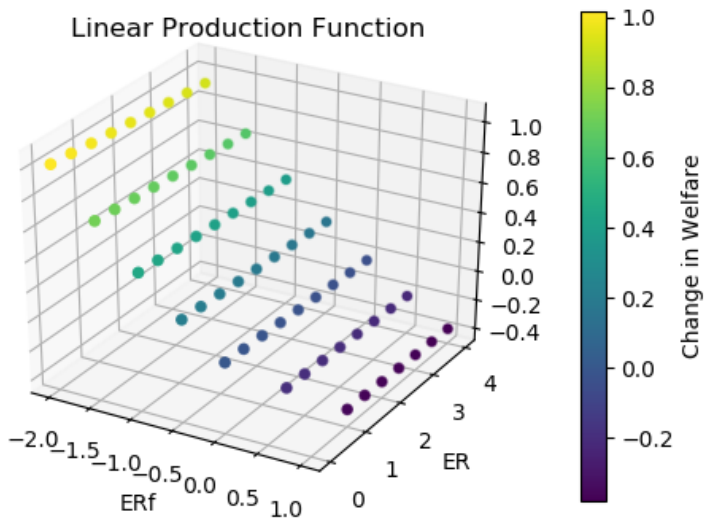

- ▶ Specify pairs of values for μ (resp. β) and γ in the linear (resp. Cobb-Douglas) case consistent with $\mathbb{E}[R] \in [0\%; 4\%]$ and $R^f \in [-2\%; 1\%]$

PAYGO: Fixed transfers, Blanchard (2019)

- **Policy 1:** $T_t = \tau l^* \forall t$. Calibration: $\tau = 5\%$.

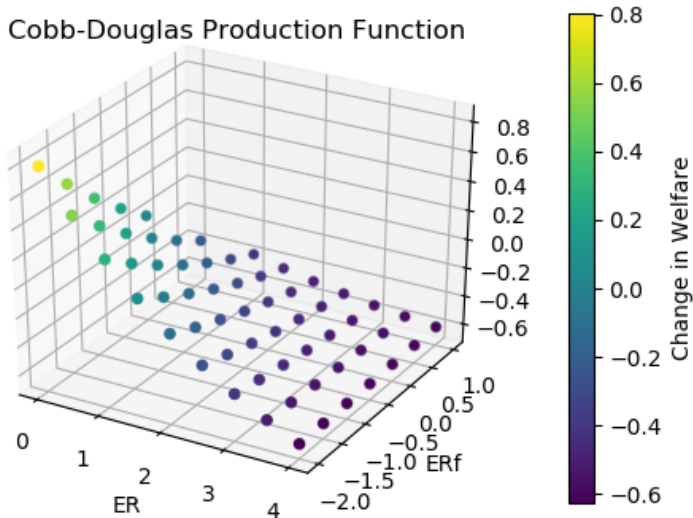

PAYGO: Fixed transfers, Blanchard (2019)

Figure 1a - Fixed transfer equal to 5% ISS (Policy 1)

PAYGO: Fixed transfers, Blanchard (2019)

Figure 1b - Fixed transfer equal to 5% ISS (Policy 1)

PAYGO: Fixed transfers, Blanchard (2019)

- **Policy 1:** $T_t = \tau l^* \forall t$. Calibration: $\tau = 5\%$.

Figure 1a - Fixed transfer equal to 5% ISS (Policy 1)

Figure 1b - Fixed transfer equal to 5% ISS (Policy 1)

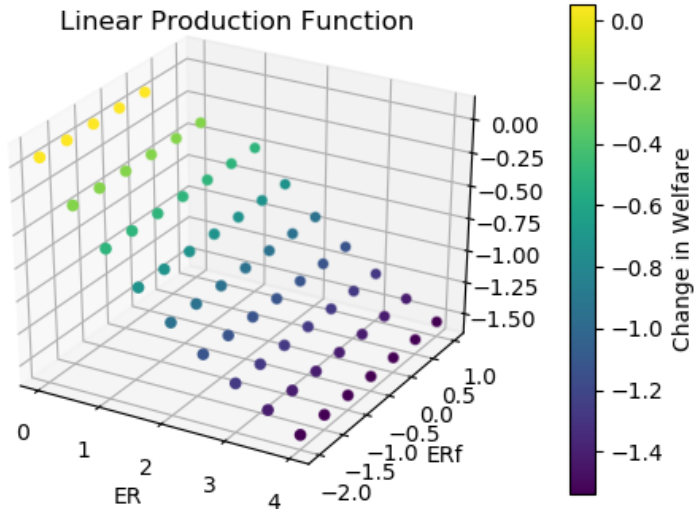

- Intuition: the policy offers a safe asset with a net return of 0% while agents were indifferent at the margin between investing in the risky or the risk-free asset
- In GE, lower capital accumulation, higher $\mathbb{E}[R]$ and thus higher R^f , policy less attractive

PAYGO: Stochastic transfers

- **Policy 3:** $T_t = \tau W_t \forall t$. Calibration: $\tau = 5\%$.

PAYGO: Stochastic transfers

Figure 3a - Stochastic transfer equal to 5% W (Policy 3)

PAYGO: Stochastic transfers

Figure 3b - Stochastic transfer equal to 5% W (Policy 3)

Cobb-Douglas Production Function

PAYGO: Stochastic transfers

- **Policy 3:** $T_t = \tau W_t \forall t$. Calibration: $\tau = 5\%$.

Figure 3a - Stochastic transfer equal to 5% W (Policy 3)

Figure 3b - Stochastic transfer equal to 5% W (Policy 3)

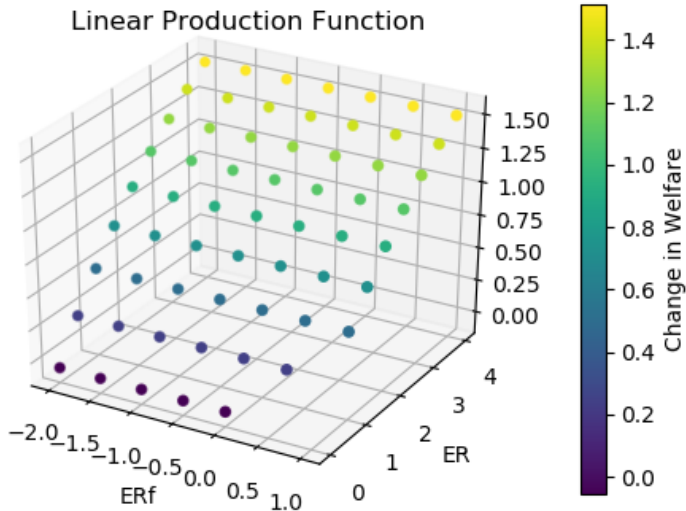

- Intuition: the policy offers a risky asset with an average expected net return of 0% and same uncertainty (returns to capital and labor perfectly correlated)
- In GE, lower capital accumulation, higher $\mathbb{E}[R]$, policy less attractive

Wage Subsidies

- **Policy 5:** $T_t = \tau W_t \forall t$. Calibration: $\tau = -5\%$.

Wage Subsidies

Figure 5a - Wage subsidy equal to 5% W (Policy 5)

Wage Subsidies

Figure 5b - Wage subsidy equal to 5% W (Policy 5)

Wage Subsidies

- **Policy 5:** $T_t = \tau W_t \forall t$. Calibration: $\tau = -5\%$.

Figure 5a - Wage subsidy equal to 5% W (Policy 5)

Figure 5b - Wage subsidy equal to 5% W (Policy 5)

- Intuition: the policy offers the possibility to invest some extra income at an average expected return $\mathbb{E}[R]$ while the average net expected cost of this extra income is 0%
- Also, offers income diversification!
- In GE, higher capital accumulation, policy more attractive if $\mathbb{E}[R]$ high enough

Long-Run Welfare Implications

Long-Run Welfare Implications

- ▶ If the transfer is deterministic then both average risk-free and risky rates matter if the production function is Cobb-Douglas, only the risk-free rate if the production function is linear

Long-Run Welfare Implications

- ▶ If the transfer is deterministic then both average risk-free and risky rates matter if the production function is Cobb-Douglas, only the risk-free rate if the production function is linear
- ▶ If the policy intervention takes the form of a PAYGO system with stochastic transfers then only the average risky rate matters to assess steady-state welfare implications

Long-Run Welfare Implications

- ▶ If the transfer is deterministic then both average risk-free and risky rates matter if the production function is Cobb-Douglas, only the risk-free rate if the production function is linear
- ▶ If the policy intervention takes the form of a PAYGO system with stochastic transfers then only the average risky rate matters to assess steady-state welfare implications
- ▶ Tension between policies that improve welfare of future generations at the expense of current generations, and *vice versa*

Calibration

- ▶ Simulate 1,000 paths of the economy with and without intervention.
- ▶ Study the welfare implications for up to 5 generations (125 years)
- ▶ Calibration: $\mathbb{E} R = 2\%$ and $R^f = -1\%$ as in Blanchard (2019);
 $\bar{D} = 0.1725I^*$ and $D^* = 0.4D_0$

Debt Rollovers, Blanchard (2019)

- **Policy 7:** $T_t = 0 \forall t$; $D_0 = \kappa l^*$. Calibration: $\kappa = 15\%$.

Debt Rollovers, Blanchard (2019)

Figure 7.1a - Change in Welfare by Generation Debt .15 (Policy 7)
Linear Production Function

Debt Rollovers, Blanchard (2019)

- **Policy 7:** $T_t = 0 \forall t$; $D_0 = \kappa l^*$. Calibration: $\kappa = 15\%$.

Figure 7.1a - Change in Welfare by Generation Debt .15 (Policy 7)
Linear Production Function

Figure 7.2a - Debt (Share Savings) Debt .15 (Policy 7)
Linear Production Function

- For current *old* clear positive and large effect (black dot), slightly larger utility for later generations (less risky portfolio)
- Debt rollovers typically do not fail and welfare is increased throughout

Debt Rollovers, Blanchard (2019)

- **Policy 7:** $T_t = 0 \forall t$; $D_0 = \kappa l^*$. Calibration: $\kappa = 15\%$.

Debt Rollovers, Blanchard (2019)

Figure 7.1b - Change in Welfare by Generation Debt .15 (Policy 7)
Cobb-Douglas Production Function

Debt Rollovers, Blanchard (2019)

- **Policy 7:** $T_t = 0 \forall t$; $D_0 = \kappa l^*$. Calibration: $\kappa = 15\%$.

Figure 7.1b - Change in Welfare by Generation Debt .15 (Policy 7)
Cobb-Douglas Production Function

Figure 7.2b - Debt (Share Savings) Debt .15 (Policy 7)
Cobb-Douglas Production Function

- Welfare still goes up for the first young generation (by about 2 percent), but is typically negative thereafter
- In the case of unsuccessful rollovers, the adjustment implies a larger welfare loss when it happens

Transfers and Subsidies

- **Policy 8:** $T_t = \tau_I I^* + \tau_W W_t \quad \forall t$. With $\tau_I = 20\%$ and $\tau_W = -\frac{\tau_I I^*}{W^*} \%$

Transfers and Subsidies

Figure 8.1a - Change in Welfare by Generation Transfers .20 (Tax) (Policy Linear Production Function)

Transfers and Subsidies

- **Policy 8:** $T_t = \tau_I I^* + \tau_W W_t \quad \forall t$. With $\tau_I = 20\%$ and $\tau_W = -\frac{\tau_I I^*}{W^*} \%$

Figure 8.1a - Change in Welfare by Generation Transfers .20 (Tax) (Policy 8)
Linear Production Function

Figure 8.2a - Debt (Share Savings) Transfers .20 (Tax) (Policy 8)
Linear Production Function

- In all simulations, welfare goes up for all generations (by about 3 percent on average) except current *old* who are indifferent: Pareto improvement
- One-time drop in capital accumulation

Transfers and Subsidies

- **Policy 8:** $T_t = \tau_I I^* + \tau_W W_t \forall t$. With $\tau_I = 20\%$ and $\tau_W = -\frac{\tau_I I^*}{W^*} \%$

Transfers and Subsidies

Figure 8.1b - Change in Welfare by Generation Transfers .20 (Tax) (Policy Cobb-Douglas Production Function)

Transfers and Subsidies

- **Policy 8:** $T_t = \tau_I I^* + \tau_W W_t \quad \forall t$. With $\tau_I = 20\%$ and $\tau_W = -\frac{\tau_I I^*}{W^*} \%$

Figure 8.1b - Change in Welfare by Generation Transfers .20 (Tax) (Policy 8)
Cobb-Douglas Production Function

Figure 8.2b - Debt (Share Savings) Transfers .20 (Tax) (Policy 8)
Cobb-Douglas Production Function

- Again, a Pareto improvement
- Transfers imply lower capital accumulation, but the wage subsidy fosters investment (see proof) thus limiting the adverse price effect

Debt Rollovers and Subsidies

- **Policy 9:** $T_t = \tau W_t \ \forall t$; $D_0 = \kappa l^*$. Calibration: $\kappa = 10\%$; $\tau = -\frac{D_0}{W^*}$

Debt Rollovers and Subsidies

Figure 9.1a - Change in Welfare by Generation Debt .10 (Tax) (Policy 9)
Linear Production Function

Debt Rollovers and Subsidies

Calibration: $\kappa = 10\%$; $\varkappa = 7.5\%$; $\tau = -\frac{D_0}{W^*}$

10.1b - Change in Welfare by Generation Extended Debt .10 (Tax) (Policy 10)
Cobb-Douglas Production Function

Figure 10.2b - Debt (Share Savings) Extended Debt .10 (Tax) (Policy 10)
Cobb-Douglas Production Function

- Again it is a Pareto improvement
- Debt more persistent than simple debt rollover (more akin to fixed transfers), but still decreases, thus higher SS capital level

Conclusion

- ▶ If PAYGO system with stochastic transfers then only risky rate matters
- ▶ The economy is likely to be *dynamically inefficient* in such low rate environment: PAYGO system with fixed transfers and wage subsidies are Pareto welfare improving
- ▶ The combination of a debt rollover and a wage subsidy: Pareto welfare improvement and higher level of steady-state capital
- ▶ Would be interesting to understand how the optimal size in the initial debt increase varies with different combinations of the average safe and risky rates, or to include business cycle considerations

Wage Subsidies - Proof

With linear production function:

Optimal investment decision:

$$I_t^L = \beta W_t(1 - \tau) - \frac{1 - \alpha}{\alpha} \tau(1 - \beta)$$

Result 1. Assuming $0 < \alpha, \beta < 1$, $I_t^L > I_t$ if and only if $\tau < 0$. Conversely, $I_t^L < I_t$ if and only if $\tau > 0$.

Consumption when *young* and *old* absent government intervention are:

$$C_t^y = (1 - \beta)W_t$$

$$C_{t+1}^o = R_{t+1}I_t$$

Consumption when *young* and *old* after the government intervention are:

$$C_t^{y,L} = W_t(1 - \tau) - I_t^L = (1 - \beta)[W_t(1 - \tau) + \frac{1 - \alpha}{\alpha} \tau]$$

$$C_{t+1}^{o,L} = R_{t+1}I_t^L + \tau W_{t+1}$$

Result 2. Consider two cases:

- ▶ If $R_t \geq 1$ then $C_t^{y,L} \geq C_t^y$ and $C_{t+1}^{o,L} \geq C_{t+1}^o$ if and only if $\tau < 0$.
- ▶ If $R_t \leq 1$ then $C_t^{y,L} \geq C_t^y$ and $C_{t+1}^{o,L} \geq C_{t+1}^o$ if and only if $\tau > 0$.
